

# **Aerial Adulticiding**

**Public health Entomology Research and  
Education Center**

**Jane Barber, Mike Greer FAMU**

**Mark Latham, Gail Stout Manatee County MCD**

# Characterization of permethrin flux

- Permethrin has just been labeled for aerial application in Florida Mosquito Control
- Highly toxic to aquatic non targets
- Identify interactions between primary parameters and their effects on control and non target mortality
  - meteorological change, drop size and altitude
- Here we shall only discuss deposition and non target mortality

# Mosquito Adulticiding

- In mosquito adulticiding the target is the mosquito on the wing
- Therefore we must fly when the mosquito flies
- The chemical needs to stay airborne and not deposit for two reasons
  - Chemical will be lost to the mosquitoes
  - Chemical will be available to non targets

# Deposition: Non Target Mortality

- The EPA are deeply concerned about ground deposits
- They have gathered aquatic organism end points for permethrin from which **No Observable Affect Environmental Concentrations NOAEC** are extrapolated
- We can not exceed these end points

# Experimental Protocol

08/17/2006

Hughes-500D 1097C

J. Gardner

Kontrol 30-30 0.36 oz/Acre

G9 889 Acres (2.5 Gallons)

## (Experimental Spray)

Spray Altitude - 100 Ft

Spray Speed - 105 MPH

Swath Width - 500 Ft

Offset - 0 Ft

Flow Rate - 38 oz/minute

Nozzles - 1xPJ20 + 1xPJ15 @ 500 PSI

(Approximate VMD = 30 microns)

Start Spray - 05:20 AM

End Spray - 05:30 AM

12 Runs @ 500 Ft Swath

Baseline run through center  
of circle perpendicular to wind direction

Sampling Site:  
Spinner, Bioassay Water,  
Mosquito Cage

3-D Sonic Anemometer  
(Tower)

2-D Sonic Anemometer  
(Mast)

## AIMMS-20 Met Data

Winds - ESE (120 degrees) @ 6-8 Knots

Temp 75 F

Hum 95-98%

# Deposition: Physical and biological measures

# Deposition

To date four tests have been  
conducted

Deposits and non target mortality has  
occurred on each test

# Deposition: Dose response, field dose and mortality

- EPA, Acute toxicity range for permethrin = 0.1 - 210 ppb
- Laboratory dose response shows an LC50 at 1.3 ppb our non target is very sensitive
- The bioassay and filter provides us with a deposit amount that can be extrapolated into the toxicology models

# Aquatic Organisms End Points

Table 35. Permethrin toxicity reference values (ppb of active ingredient) for aquatic organisms.

Exposure scenario	Species	Exposure duration	Toxicity reference value (ppb)	Reference
<b>Freshwater Fish</b>				
Acute	Bluegill sunfish	96 hours	LC <sub>50</sub> = 0.79 ppb	ESF3 Supplemental
Chronic	Fathead minnow	Full life cycle	NOAEC = 0.30 ppb LOAEC = 0.41 ppb	ACC 096689 Supplemental Core
<b>Freshwater Invertebrates</b>				
Acute	<i>Hexagenia bilineata</i>	48 hours	EC <sub>50</sub> = 0.1 ppb	MRID 23648 Core

Fresh water invertebrates NOAEC 0.039ppb

<b>Estuarine/Marine Fish</b>				
Acute	Atlantic silverside	96 hours	LC <sub>50</sub> = 2.2 ppb	EPA (1987) Supplemental
Chronic	Sheepshead minnow	28 day early life stage	NOAEC 0.83 ppb <sup>1</sup> LOAEC 10 ppb	Hansen <i>et al.</i> (1983) Supplemental
<b>Estuarine/Marine Invertebrates</b>				

Marine invertebrates NOAEC 0.011ppb

Chronic	Mysid shrimp	30 day life cycle	Mortality: NOAEC = 0.011 ppb LOAEC = 0.024 ppb	MRID 41315701 Supplemental study
---------	--------------	-------------------	--	----------------------------------

<sup>1</sup> The estuarine/marine chronic value is extrapolated by using an acute/chronic ratio method of available data from similar species (0.79/0.30 : 2.2/x = 0.83 ppb).

# Concentration of deposits

- The NOAEC is a concentration the environmental toxicologists use with four different water body depths
  - 6" pool
  - 1' pool
  - 1m pool
  - 2m pool
- The 2m pool is the standard water body used in the modeling of appropriate nozzle systems

# Concentration in a 6" pool

# Concentration in a 1' pool

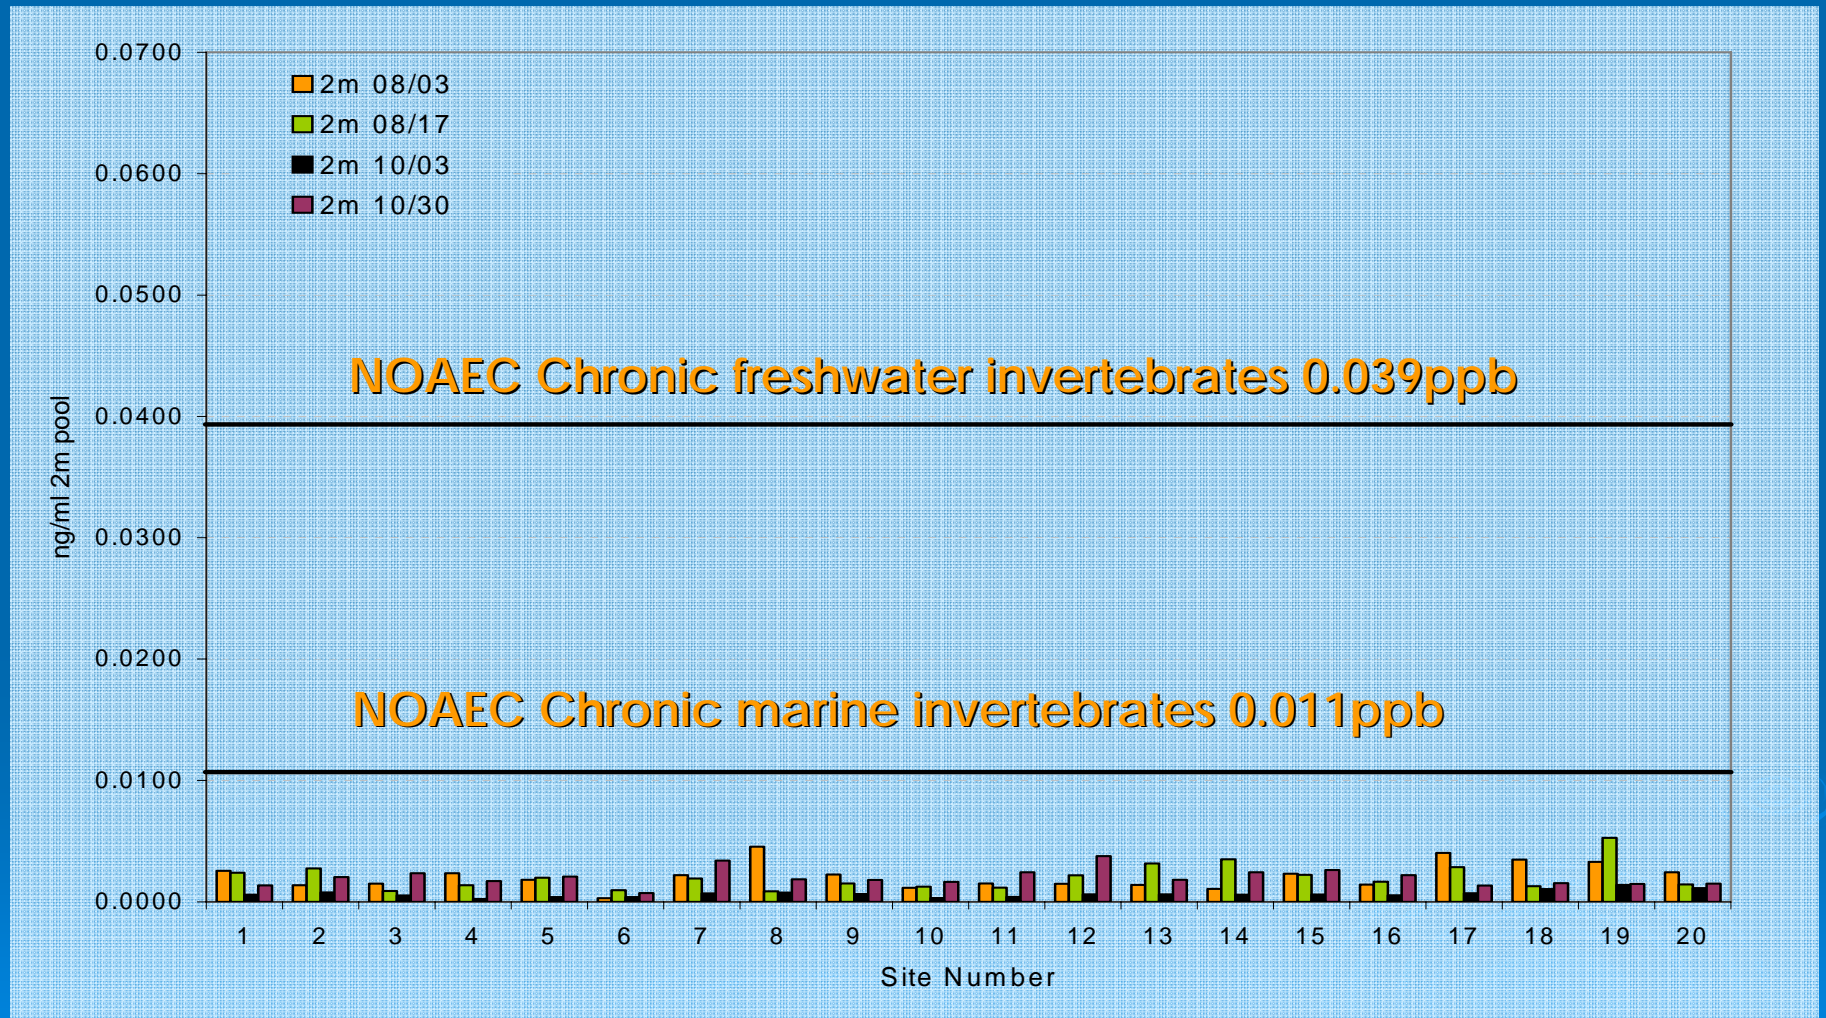

# Concentration in a 1m pool

# 2m = eco-toxicological models

# Vortical decay

- The stability at time of application strongly correlated with ground deposit values
- Neutral nights have increased wind speed and therefore vortical decay
  - There is a reduction in the time/distance which the spray is entrained before dissipation
- Stable nights the vortices decay slowly entraining more chemical forcing it into the ground

# Tabulated Averages

- To be within the NOAEC 0.011ppb for marine invertebrates in shallow water you must have a Ri of close to 0.02 or appreciable wind
- If all water bodies are 1m or more in depth marine invertebrates unharmed
- All applications were safe for fresh water invertebrates NOAEC 0.039ppb

	6 inches	1 foot	1 meter	2 meters	Ri	U 7m m/s	U 2m m/s	q (m/s)	Mortality
3-Aug	0.0278	0.0139	0.0042	0.0021	0.19	1.16	0.14	0.39	99
17-Aug	0.0267	0.0133	0.0041	0.0020	0.33	0.7	0.27	0.44	85
3-Oct	0.0085	0.0043	0.0013	0.0006	0.02	2.04	0.38	1.08	2
30-Oct	0.0263	0.0131	0.0040	0.0020	0.37	0.96	0.06	0.34	43

# Summary: Preliminary Thoughts

- **Stable nights slow vortical decay rate**
  - **Deposits:** Vortices remain and entrain significant spray volume, meaning more chemical is physically forced down by the air craft, chemical not available to control mosquitoes
- **Neutral nights increased vortical decay**
  - **Deposits:** Vortices decay rapidly breaking above the canopy letting air currents take a significant portion of the spray, chemical available to control mosquitoes

# Further Work

- Test an out of ground effect altitude of 150ft
- Then increase the drop size distribution and re-investigate 100 and 150ft
- We are going to add a deposited droplet distribution measure, slides on ground
- Ultimately we will be working with a mono-sized droplet generator isolating the parameter of drop size
  - Meteorology is the only variable

# **Any Questions ?**
